## Abstract

**Key words:** spectral libraries — flux calibration — filters

### 1 Filter profiles

The filter profiles are shown in Fig. 1.

### 2 Determination of AB magnitudes

AB magnitudes were obtained by integrating over the spectra convolved with the filter response. Two codes were used for obtaining and testing the magnitudes: the pyphot code by Dr. Feausneau and Maria's IDL code.

By definition

$$mag_{AB} = -2.5 \log_{10}(\bar{f}_\nu) - 48.60 \quad (1)$$

#### 2.1 Calculation in IDL

AB magnitudes were obtained by integrating over the spectra convolved with the filter response.

By definition

$$mag_{AB} = -2.5 \log_{10}(\bar{f}_\nu) - 48.60 \quad (2)$$

In the IDL code the formulation by Bessell & Murphy (2012) was implemented.

$$mag_{AB} = -2.5 \log_{10} \frac{\int f_\lambda(\lambda) S(\lambda) \lambda d\lambda}{\int S(\lambda) c \delta\lambda / \lambda} - 48.60 \quad (3)$$

$f_\lambda(\lambda)$  is in  $\text{erg cm}^{-2} \text{s}^{-1} \text{\AA}^{-1}$ ,  $\lambda$  is in  $\text{\AA}$ , and the light speed  $c$  is in  $\text{\AA s}^{-1}$

The integration is performed with the trapezoidal method in IDL.

#### 2.2 pyphot code

The AB magnitudes are obtained using the formulation by Koornneef et al. (pyphot link).

$$mag_{AB} = -2.5 \log_{10}(\bar{f}_\lambda) - 2.5 \log_{10}(\lambda_p^2 / c) - 48.60 \quad (4)$$

$$\bar{f}_\lambda = \frac{\int f_\lambda(\lambda) S(\lambda) \lambda d\lambda}{\int S(\lambda) \lambda d\lambda} \quad (5)$$

$$\lambda_p^2 = \frac{\int S(\lambda) \lambda d\lambda}{\int S(\lambda) d\lambda} \quad (6)$$

The speed of light  $c$  and  $\lambda_p$  must be expressed in matching units. The program pyphot is able to automatically transform the units, as long as they are indicated.

$\lambda$  is the wavelength,  $f_\lambda(\lambda)$  is the observed flux density, and  $S(\lambda)$  is the photonic passband (response function).

The integration is performed with the numpy trapz (np.trapz) function.

### 3 Datasets

The synthetic magnitudes were measured on a subsample of 133 SPSSv3.4 stars, results are in Figs. 2 and 3.

The 61 PVL stars are shown in Figs. 4 and 5.

The CALSPEC stars are shown in Figs. 6 and 7.

#### 3.1 Code differences

Using the 133 SPSSv3.4 stars and the results from python and IDL, the measured differences are listed in Table 1.

For the PVL, 62 stars are used and the differences are in Table 2.

Fig. 1. BEPI-COLOMBO filter profiles.

For the CALSPEC, the differences are listed in Table 4. Now, the table looks nice; the problem was coming from some negative fluxes present in some spectra. The following spectra were removed 2MASSJ00361617+18211, 2MASSJ05591914-14044, BD-11.3759, 2MASSJ17583798+66465, VB8, SF1615+001A, WD1057+719, LDS749B, and hz43. Now, only 99 CALSPEC spectra are used, and 93 of them have BP/RP spectra.

Two changes were implemented:

- Added a dot in the HRIC-PAN filter.
- The codes was modified to consider flux > 0 (rather than flux != 0).
- Six CALSPEC spectra were removed for being very poor in the blue side.
